

TC 6.0 Text editors

In the last module, you used nano, which is a ubiquitous file editor that runs at the root of your machine, meaning it has most permissions satisfied.

You may have learned about the **chmod** command and the rwx format, which is useful here.

What we are seeking beyond nano is what is known as WYSIWYG editors:

“What you see is what you get”

Here are several other text editors you may find useful:

Mac:

Subethaedit

TextEdit (part of OSX)

bbedit

itext express

Linux:

gedit

atom

sublime text

GNU emacs

Geany (comes on raspberry pi)

Windows:

sublime text

atom

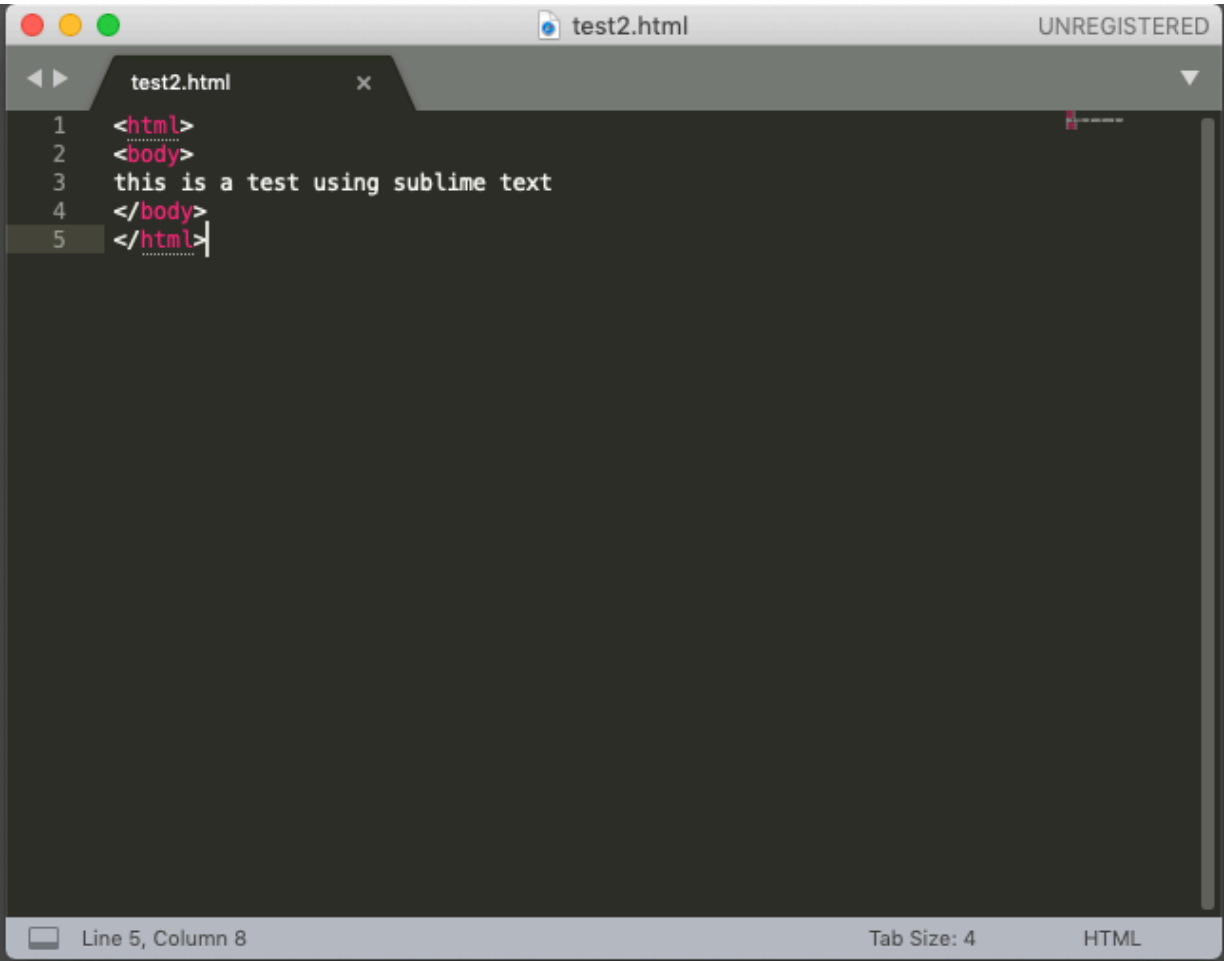

notepad++

textmate

coda

Test a few of these out, creating both text documents with the .txt suffix (extension) and some html code with the .html suffix.

Here's what sublime text looks like:

The screenshot shows a code editor window titled "test2.html" with a status bar indicating "UNREGISTERED". The editor contains the following HTML code:

```
1 <html>
2 <body>
3 this is a test using sublime text
4 </body>
5 </html>
```

The status bar at the bottom shows "Line 5, Column 8", "Tab Size: 4", and "HTML".

and how it shows up on safari:
